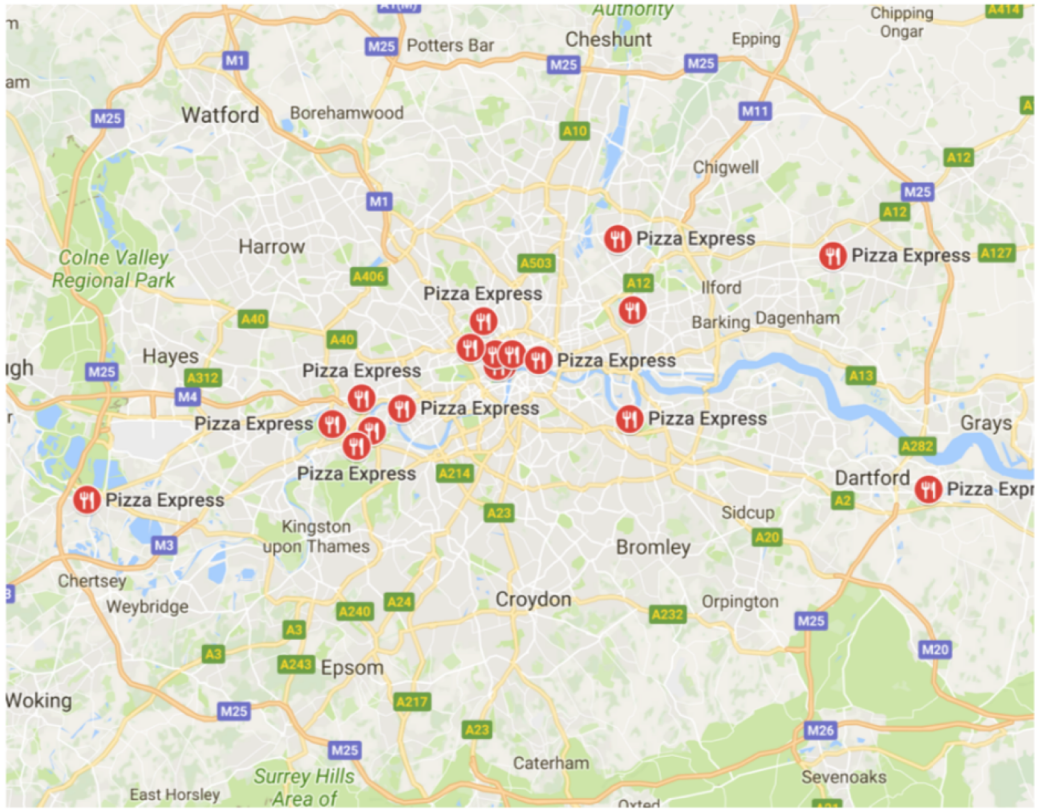
Lecture overview

- A gentle introduction: ML for the real world
- Linear models: the regression case
- Linear models: the classification case
- Figures of Merits: visual evaluation of solution effectiveness
- Why ML works: a bit of Learning Theory
- Overfitting: how to fool the linear regression
- Regularization

Machine learning for the real world

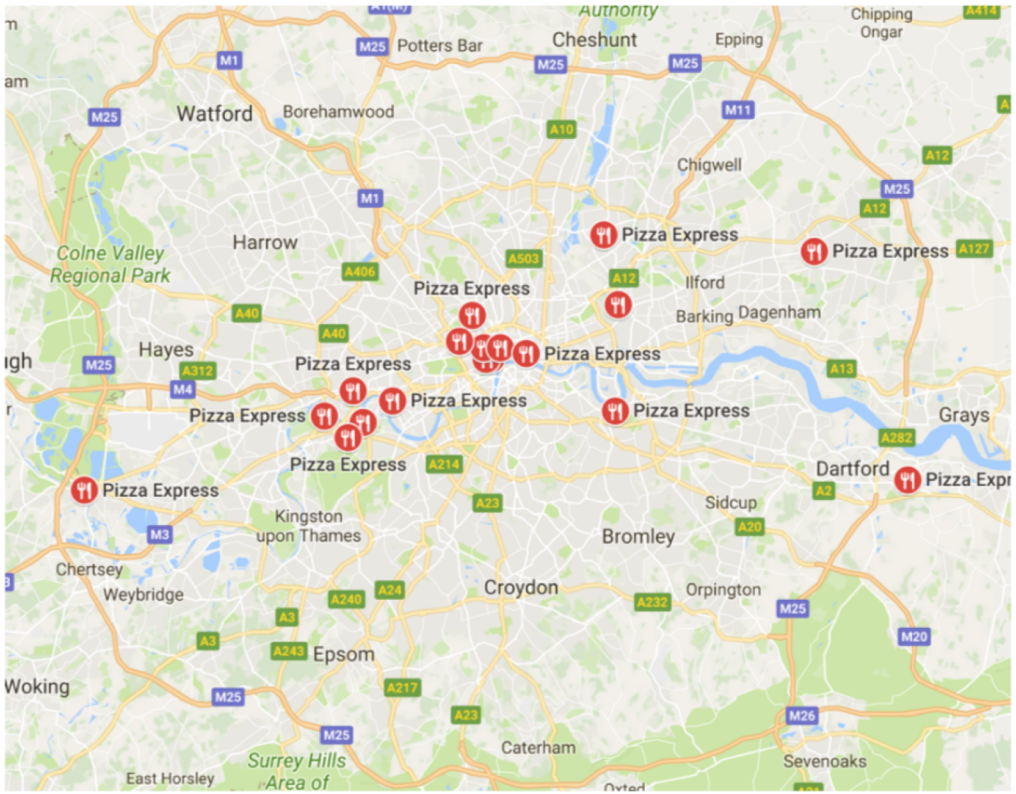
- You own a pizza restaurant chain
- Where to open the next restaurant?
- No revenue laws (of the kind $\vec{\mathbf{F}} = m\vec{\mathbf{a}}$) exist!
- Is there any stats on restaurant revenue?



Machine learning for the real world

- Use stats!
- Properties and revenues of existing restaurants:

Id	Location	Revenue
1	51.472866,-0.2588277	$1.1M
2	51.4865675,-0.2210999	$2.23M
. . .	. . .	. . .
20	51.4334641,-0.5146408	$0.59



Some notation

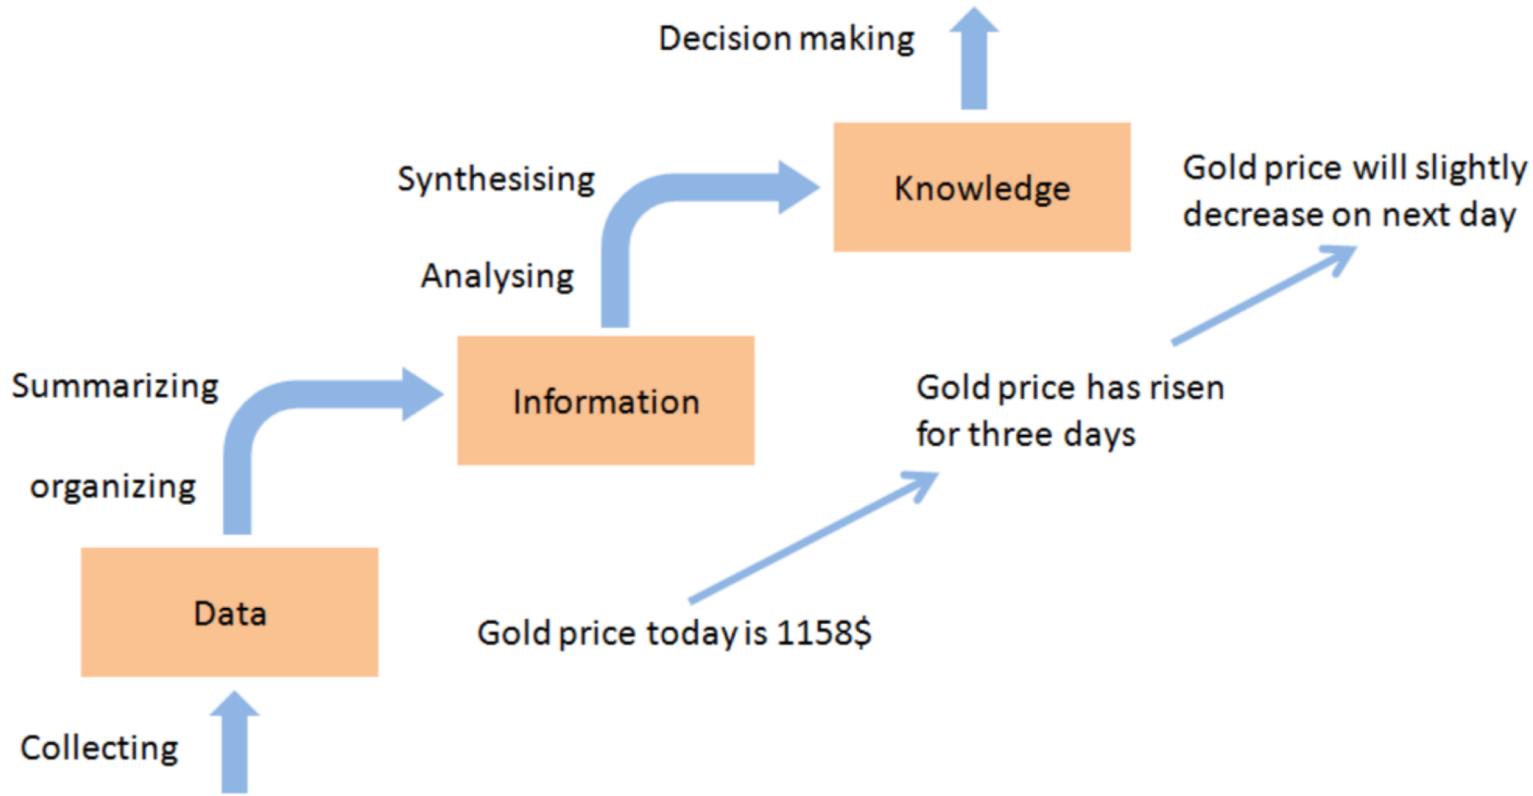
- Object space $\mathbb{X} = \mathbb{R}^2$: restaurant location (also known as the feature space)
- Target space $\mathbb{Y} = \mathbb{R}$: restaurant revenue
- Training set $X^\ell = \left\{(\mathbf{x}_i, y_i)\right\}_{i=1}^{\ell}$ (known locations and revenues for existing restaurants)
- **The goal:** estimate $y \in \mathbb{Y}$ for a new $\mathbf{x} \in \mathbb{X}$ (estimate revenue for a proposed location)

Expert knowledge and physical models VS machine learned models

- Would one want to apply machine learning for . . .
  - . . . Newton's mechanics?
  - . . . suggesting music to radio listeners?
  - . . . sorting integers?
  - . . . controlling steel production?
  - . . . sorting strawberries?
- Criteria for machine learning to be applied in a dependency recovery setting:
  - No prior knowledge for the dependency exists
  - The dependency has a complex form too hard for manual examination
  - A sample from the dependency of sufficiently large size is available

What is machine learning about?

- Inference of statistical dependencies which give us ability to predict
- Data is cheap, knowledge is precious



Feature vectors

- Computers cannot operate objects of the real world directly
- Need features describing the objects ($\mathbf{x} = (\text{lat}, \text{lon})$ for the restaurant)

- In real applications such as fraud detection, feature engineering is the most complex task
- Many papers on the problem

- Machine location (e.g. beside supermarket, latitude, longitude), brand, and age
- Customer demographic (e.g. postcode) and behavioral information
- Card type (e.g. Visa, supplementary, issued yesterday) and usage
- Session/transaction day-of-week, time-of-day, keystrokes (e.g. number of login attempts), transaction type, and amount

Possible kinds of features: some more notation

- Binary: $x \in \{0, 1\}$ (are you a member of a terrorist organization?)
- Real-valued: $x \in \mathbb{R}$ (customer income)
- Categorical: $x \in S$ where $|S| = n$ and order of elements in S does not matter (customer postcodes)
- Ordinal: $x \in S$ where $|S| = n$ and order of elements in S does matter (old $<$ renovated $<$ new for house price prediction)
- Structured: images (customer photo in the fraud detection task)

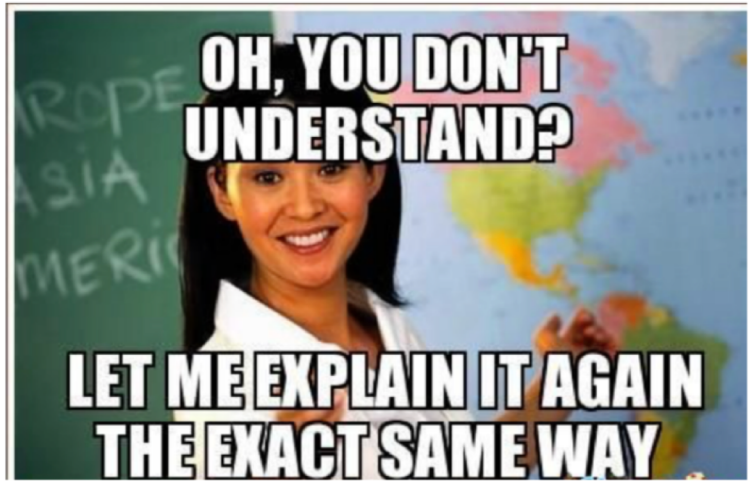
Kinds of machine learning tasks

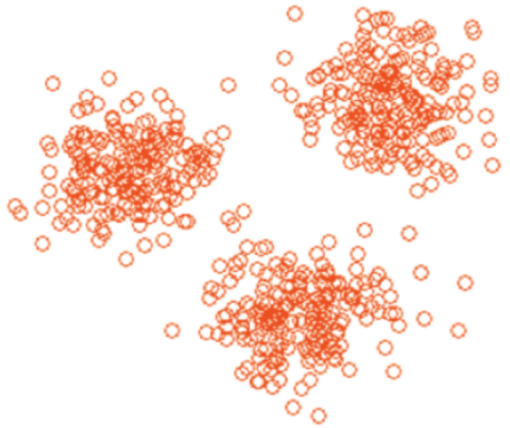
- Supervised learning

  - Regression, (multi-class/multi-label) classification, semi-supervised learning

- Unsupervised learning

  - Clustering, density estimation, dimensionality reduction, visualization





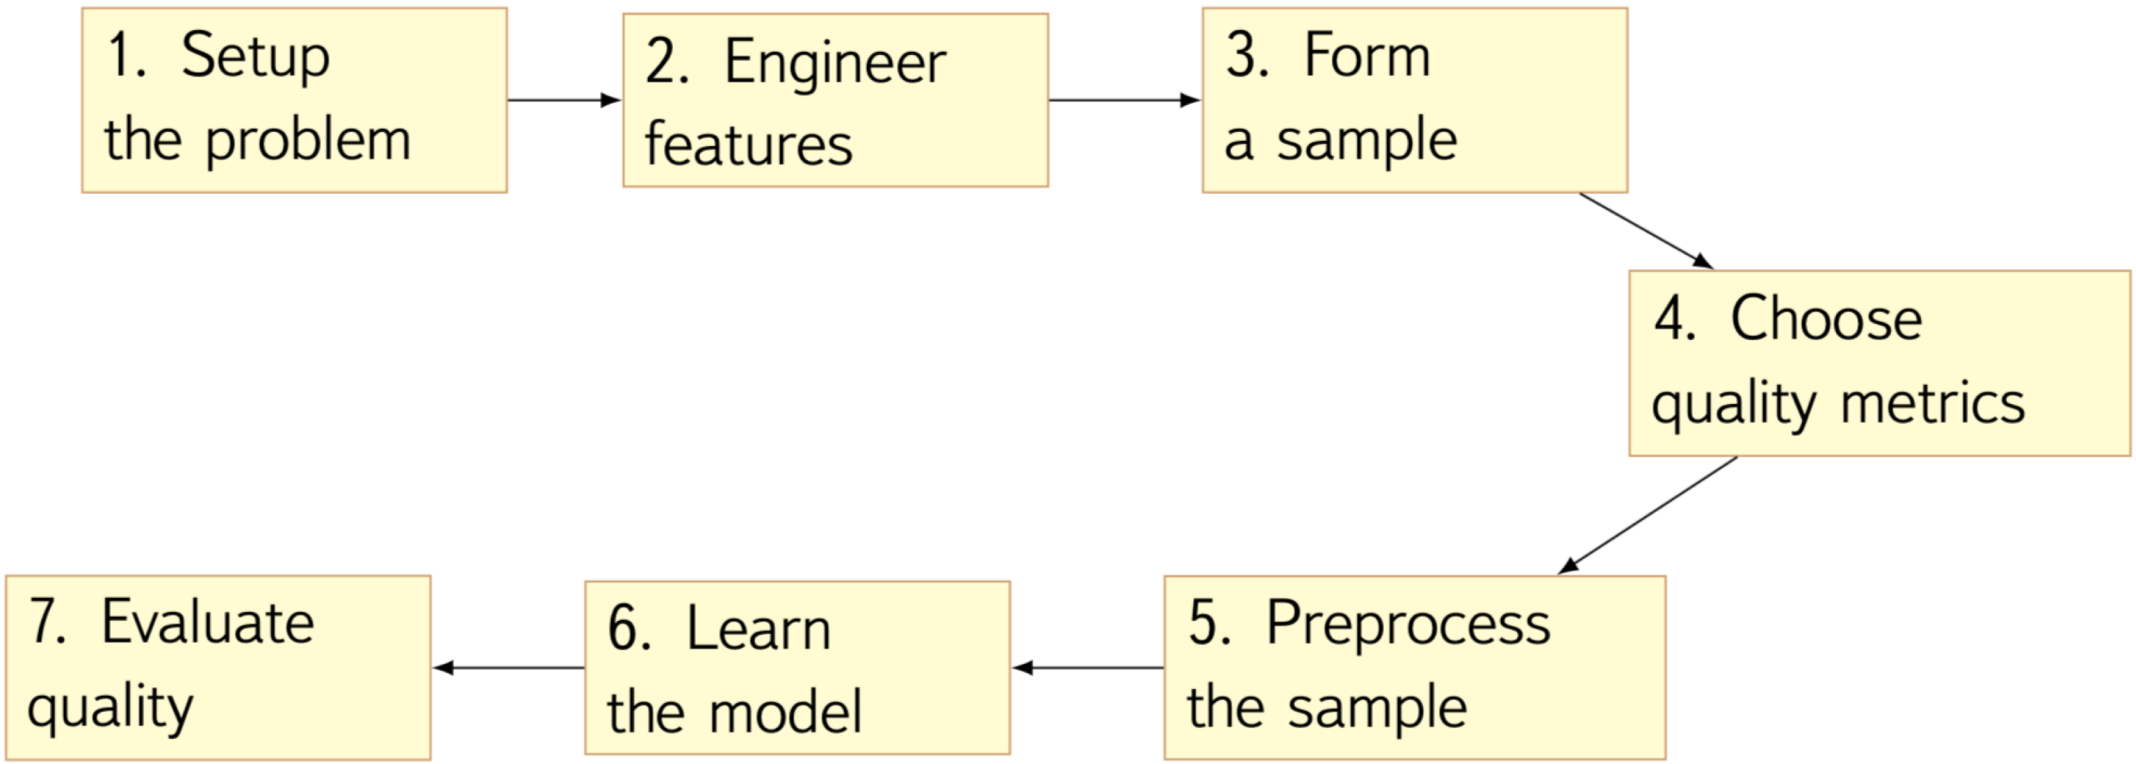
Yet more notation

- An unknown distribution D generates instances $(\mathbf{x}_1, \mathbf{x}_2, \ldots)$ independently
- An unknown function $f : \mathbb{X} \to \mathbb{Y}$ generates responses $(y_1, y_2, \ldots)$ for them such that $y_i = f(\mathbf{x}_i), i = 1, 2, \ldots$
- The machine learning problem: choose a plausible hypothesis $h : \mathbb{X} \to \mathbb{Y}$ from the hypothesis space $\mathbb{H}$
- The error of a hypothesis h is the deviation from the true f measured by the loss function (an example for regression):

$$Q(h, X^\ell) = \frac{1}{\ell} \sum_{i=1}^{\ell} (f(\mathbf{x}_i) - h(\mathbf{x}_i))^2$$

- Learning: the search for the optimal hypothesis $h \in \mathbb{H}$ w. r. t. the fixed loss function

The machine learning pipeline



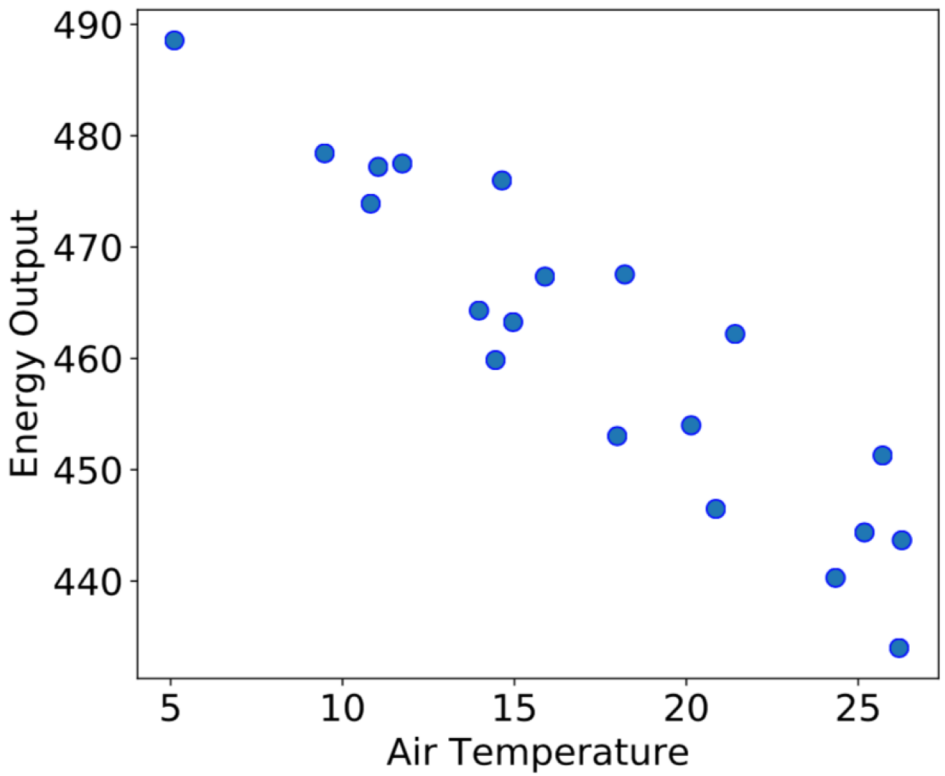
Linear models for regression

Univariate linear regression

- A single feature (regressor) x:
  Air Temperature
- A single dependent variable y:
  Energy Output
- Training set $X^\ell = \left\{(x_i, y_i)\right\}_{i=1}^{20}$
- The regression model:

$$y_i = h(x_i; \mathbf{w}) + \varepsilon_i$$

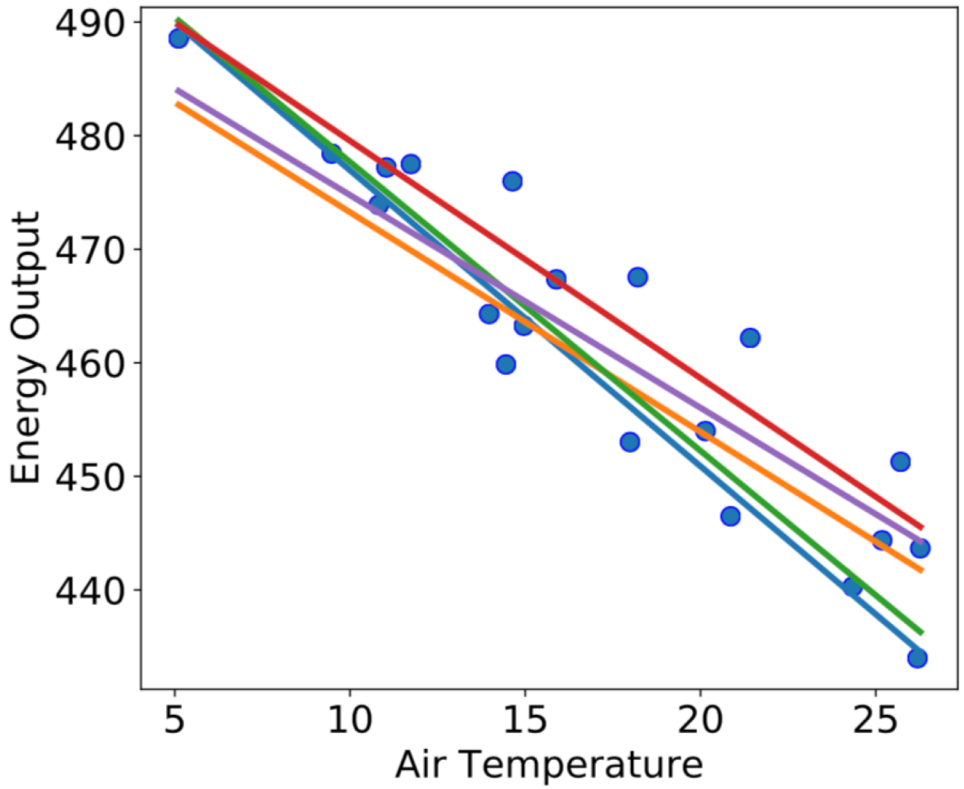
- Linear model: $y_i = w_1 x_i + w_0 + \varepsilon_i$
- The goal: given X^ℓ, find $\mathbf{w} = (w_1, w_0)$



Univariate linear regression

- Which fit to choose?
- With the linear model being fixed, depends on the data and the loss function!
- Mean square (L2) loss (MSE):

$$Q(h, X^\ell) = \frac{1}{\ell} \sum_{i=1}^{\ell} (y_i - h(x_i))^2$$



Some other evaluation metrics for regression

- Mean square (L2) loss (MSE): $\mathrm{MSE}(h, X^\ell) = \frac{1}{\ell} \sum_{i=1}^{\ell} (y_i - h(x_i))^2$
- Root MSE: $\mathrm{RMSE}(h, X^\ell) = \sqrt{\frac{1}{\ell} \sum_{i=1}^{\ell} (y_i - h(x_i))^2}$
- Coefficient of determination: $R^2(h, X^\ell) = 1 - \frac{\sum_{i=1}^{\ell} (y_i - h(x_i))^2}{\sum_{i=1}^{\ell} (y_i - \mu_y)^2}$

  with $\mu_y = \frac{1}{\ell} \sum_{i=1}^{\ell} y_i$
- Mean absolute error: $\mathrm{MAE}(h, X^\ell) = \frac{1}{\ell} \sum_{i=1}^{\ell} |y_i - h(x_i)|$

Univariate linear regression

› With the loss fixed, the linear problem reduces to optimization:

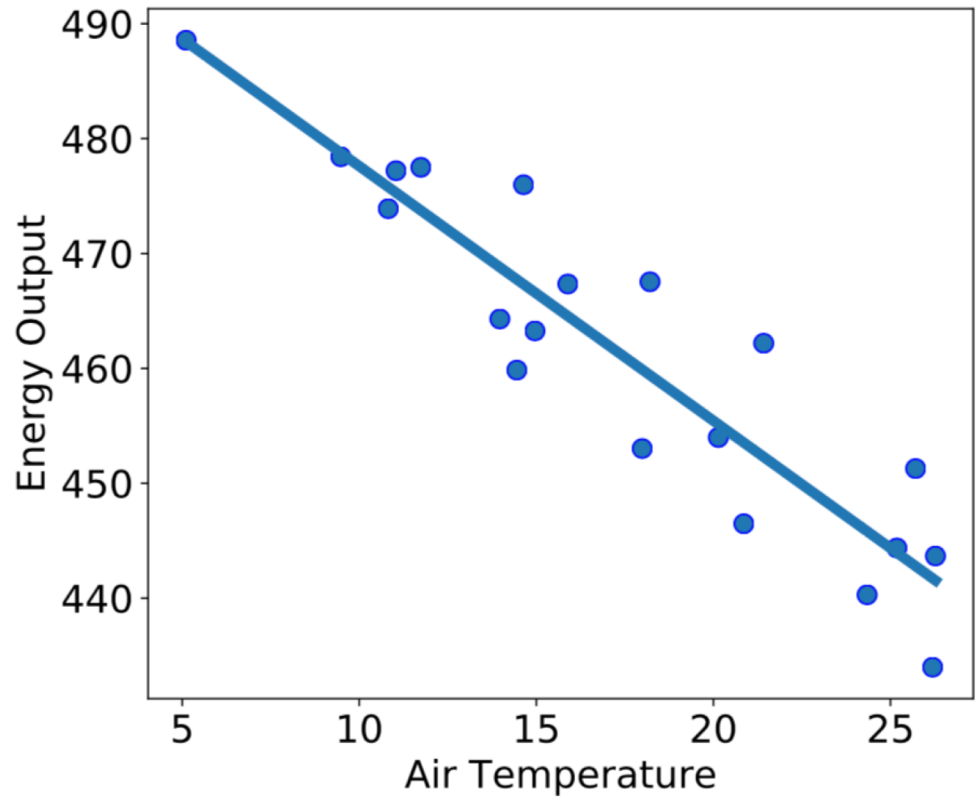
$$\frac{1}{\ell}\sum_{i=1}^{\ell}(y_i - w_1 x_i - w_0)^2 \to \min_{(w_0,w_1)\in\mathbb{R}^2},$$

to which an analytical solution is available

$$\widehat{w}_1 = \frac{\sum_{i=1}^{\ell}(x_i - \mu_x)(y_i - \mu_y)}{\sum_{i=1}^{\ell}(x_i - \mu_x)^2},$$

$$\widehat{w}_0 = \mu_y - \widehat{w}_1\mu_x$$

with $\mu_x = \frac{1}{\ell}\sum_{i=1}^{\ell} x_i, \quad \mu_y = \frac{1}{\ell}\sum_{i=1}^{\ell} y_i$



Multivariate linear regression

- Multiple features (regressors) $\mathbf{x}_i = (x_{1i}, \dots x_{di})$ available for each y_i
- The model:

$$y_1 = w_1 x_{11} + \dots w_d x_{d1} + \varepsilon_1,$$
$$y_2 = w_1 x_{12} + \dots w_d x_{d2} + \varepsilon_2,$$
$$\dots$$
$$y_\ell = w_1 x_{1\ell} + \dots w_d x_{d\ell} + \varepsilon_\ell,$$

is often written in matrix-vector form as

$$\begin{bmatrix} y_1 \\ \vdots \\ y_\ell \end{bmatrix} = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{d1} \\ \vdots & \vdots & \ddots & \vdots \\ x_{1\ell} & x_{2\ell} & \dots & x_{d\ell} \end{bmatrix} \begin{bmatrix} w_1 \\ \vdots \\ w_d \end{bmatrix} + \begin{bmatrix} \varepsilon_1 \\ \vdots \\ \varepsilon_\ell \end{bmatrix} \quad \longleftrightarrow \quad \boldsymbol{y} = \boldsymbol{X}\mathbf{w} + \boldsymbol{\varepsilon}$$

Multivariate linear regression: the solution

› The problem: minimize MSE

$$Q(h, X^l) = \sum_{i=1}^{\ell} \Big(y_i - \sum_{k=1}^{d} w_k x_{ki}\Big)^2 \equiv \|\boldsymbol{y} - \boldsymbol{X}\mathbf{w}\|^2 \to \min_{\mathbf{w}\in\mathbb{R}^d}$$

› Solve analytically via computing the gradient

$$\nabla_{\mathbf{w}} \|\boldsymbol{y} - \boldsymbol{X}\mathbf{w}\|^2 = 2(\boldsymbol{y} - \boldsymbol{X}\mathbf{w})\boldsymbol{X} = 0$$

› The solution

$$\mathbf{w}^* = (\boldsymbol{X}^\intercal \boldsymbol{X})^{-1} \boldsymbol{X}^\intercal \boldsymbol{y}$$

A quick intro into the Numerical Optimization

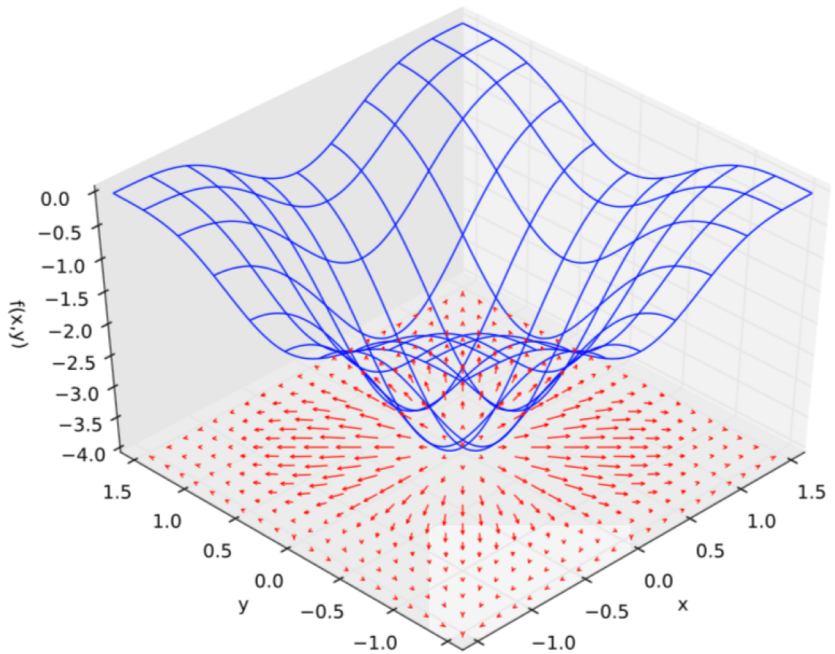
› Consider the optimization problem in $\mathbb{R}^d$

$$f(\mathbf{x}) \to \min_{\boldsymbol{x} \in \mathbb{R}^d} \qquad \text{(such as } \sum_{i=1}^{\ell} \Big(y_i - \sum_{k=1}^{d} w_k x_{ki} \Big)^2 \to \min_{\boldsymbol{w} \in \mathbb{R}^d} \text{)}$$

› In general, solved using the numerical methods such as the gradient descent

› Gradients: directions in $\mathbb{R}^d$ pointing towards steepest function increase

$$\nabla_{\mathbf{x}} f(\mathbf{x}) \equiv \left(\frac{\partial f(\mathbf{x})}{\partial x_1}, \ldots, \frac{\partial f(\mathbf{x})}{\partial x_d} \right)$$



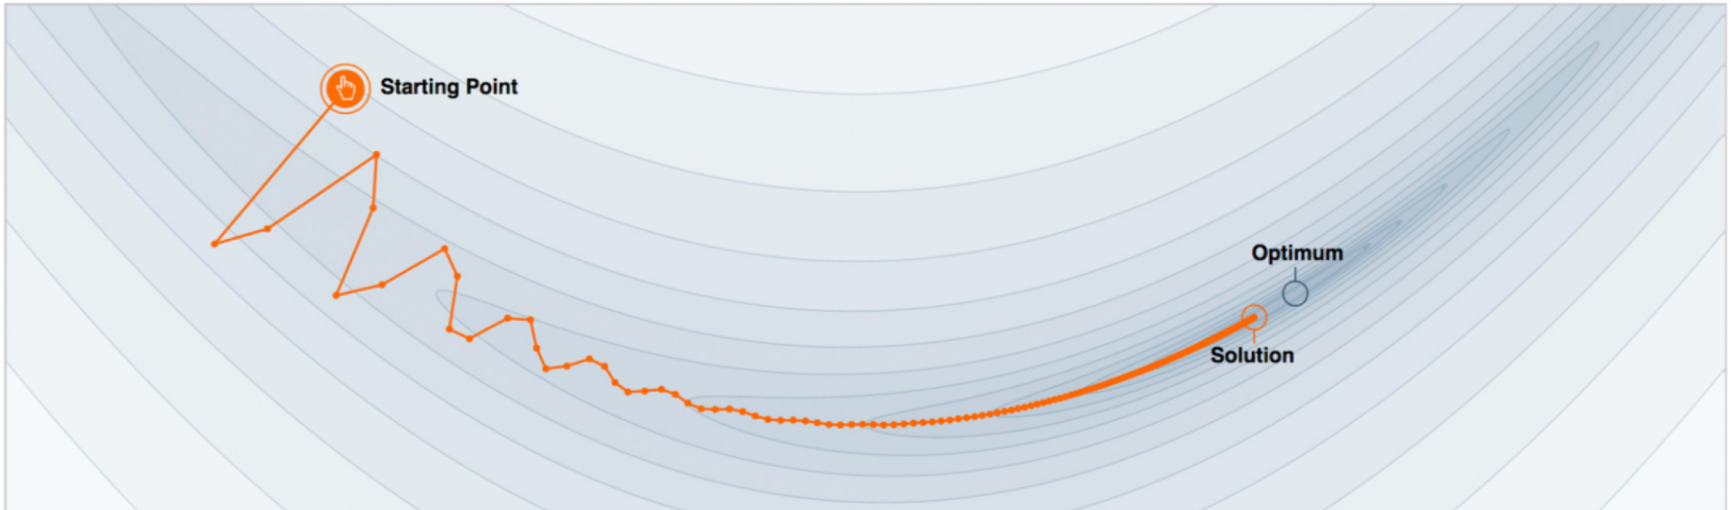
The gradient descent algorithm

› The gradient descent procedure iterates from $\mathbf{x}^{(0)}$ as

$$\mathbf{x}^{(k)} \leftarrow \mathbf{x}^{(k-1)} - \alpha_k \nabla_{\mathbf{x}} f(\mathbf{x}^{(k-1)})$$

with α_k controlling the kth step size

› For smooth convex functions with a single minimum $\mathbf{x}^*$, k steps of gradient descent achieve accuracy $f(\mathbf{x}^{(k)}) - f(\mathbf{x}^*) = \mathcal{O}(1/k)$

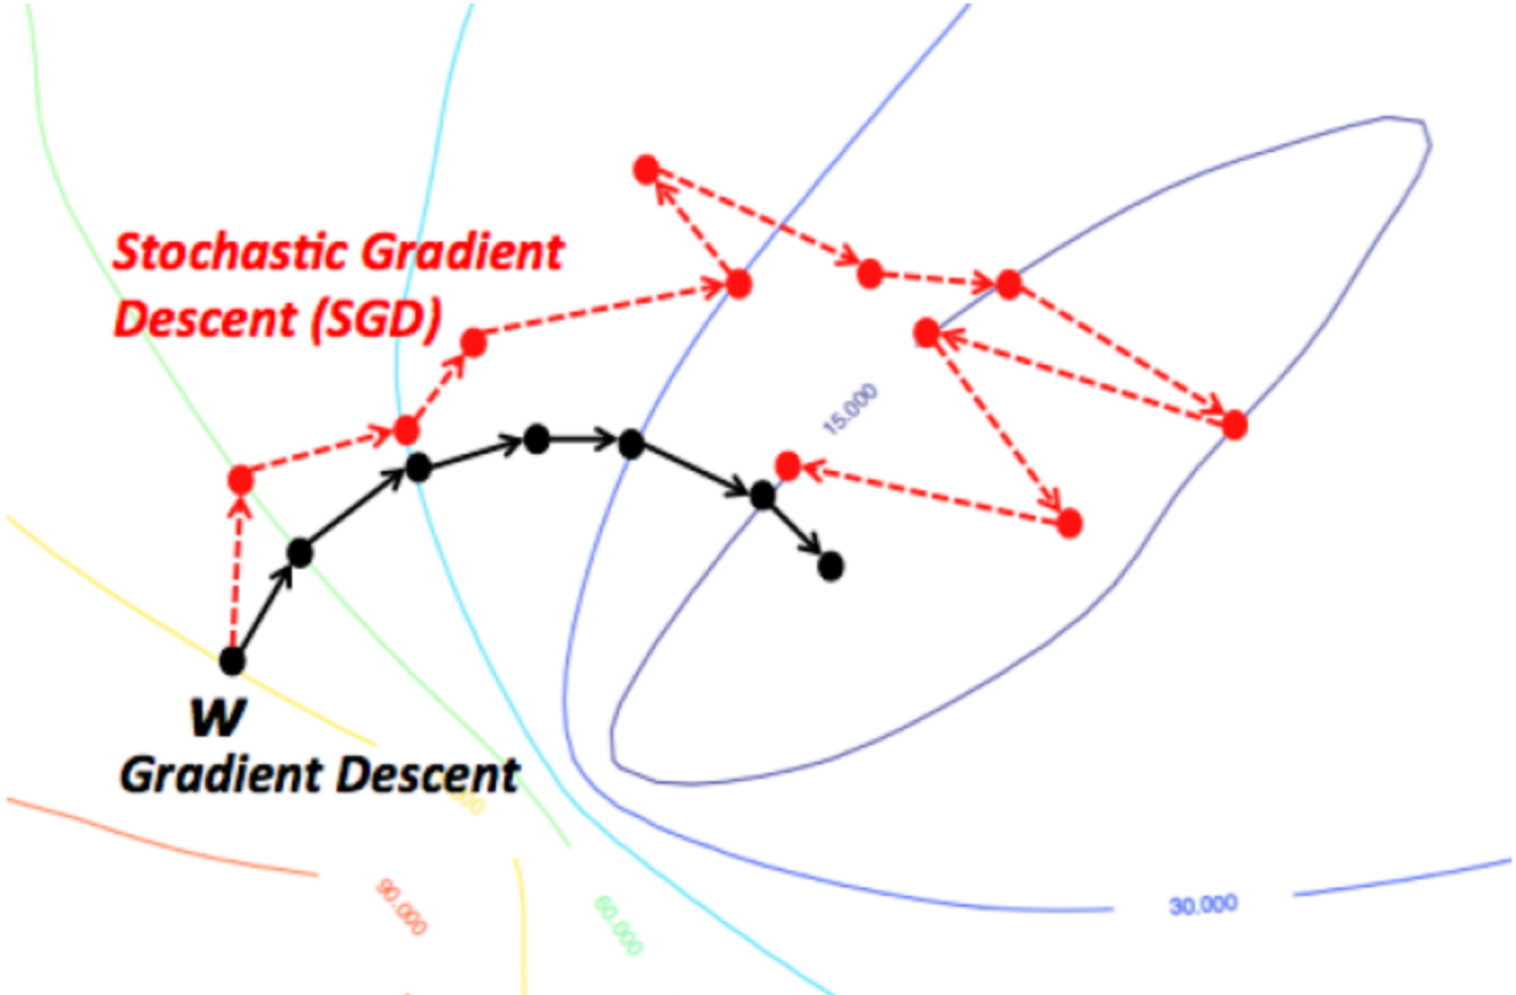


The stochastic gradient descent algorithm

- Machine learning: many additive targets $f(\mathbf{w}) = \sum_{i=1}^{\ell} f_i(\mathbf{w})$,

  computationally inefficient for large ℓ
- Use subsamples for gradient estimation: the Stochastic Gradient Descent (SGD)
  1. Pick $i_k \in \{1, \ldots, \ell\}$ at random;
  2. Compute $\mathbf{w}^{(k)} \leftarrow \mathbf{w}^{(k-1)} - \alpha_k \nabla_{\mathbf{w}} f_{i_k}(\mathbf{w}^{(k-1)})$
- For smooth convex functions with a single minimum $\mathbf{x}^*$, k steps of SGD achieve accuracy $f(\mathbf{w}^{(k)}) - f(\mathbf{w}^*) = \mathcal{O}(1/\sqrt{k})$
- Batch, variance reduction, momentum hacks available to improve the convergence rate to $\mathcal{O}(1/k)$

Gradient descent vs stochastic gradient descent



Linear models for classification

Linear models for classification

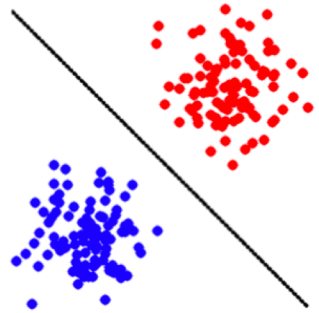
- An unknown distribution D generates instances $(\mathbf{x}_1, \mathbf{x}_2, \ldots)$
- An unknown function $f : \mathbb{X} \to \mathbb{Y}$ generates labels $(y_1, y_2, \ldots)$ for them such that $y_i = f(\mathbf{x}_i)$, and $y_i \in \{-1, +1\}$
- The classification problem: choose a plausible hypothesis (classifier) $h : \mathbb{X} \to \mathbb{Y}$ from the hypothesis space $\mathbb{H}$
- The error of the classifier h is the probability (over D) that it will fail

$$Q(h, D) = \Pr_{\mathbf{x} \sim D}[f(\mathbf{x}) \neq h(\mathbf{x})]$$

usually estimated by the accuracy metric

$$Q(h, X^\ell) = \frac{1}{\ell} \sum_{i=1}^{\ell} [f(\mathbf{x}_i) \neq h(\mathbf{x}_i)]$$

Linear models for classification



- Linear model: $h(\mathbf{x}) = \text{sign}\Big(\sum_{i=1}^{d} w_i x_i + w_0\Big) = \text{sign}\big(\mathbf{w}^\intercal \mathbf{x} + w_0\big)$
- The learning problem is discrete over $\mathbf{w} \in \mathbb{R}^d$:

$$Q(h, X^\ell) = \frac{1}{\ell} \sum_{i=1}^{\ell} [\text{sign}(\mathbf{w}^\intercal \mathbf{x}_i) \neq h(\mathbf{x}_i)] \to \min_{\mathbf{w} \in \mathbb{R}^d}$$

(cannot optimize using gradient descent)

- The solution: optimize a differentiable upper bound for $Q(h, X^\ell)$!
- $Q(h, X^\ell)$ can be written using $Q(h, X^\ell) = \frac{1}{\ell} \sum_{i=1}^{\ell} L(M_i)$

where $L(M_i) = [M_i < 0] \equiv [y_i \mathbf{w}^\intercal \mathbf{x}_i < 0]$

- Upper-bounding $L(M)$ yields upper bounds for $Q(h, X^\ell)$

The logistic regression model

- Training set $X^\ell = \{(\mathbf{x}_i, y_i)\}_{i=1}^{\ell}$ where $y_i \in \{-1, +1\}$
- We seek an algorithm h such that $h(\mathbf{x}) = \mathrm{P}(y = +1|\mathbf{x})$
- A probability that an instance $(\mathbf{x}_i, y_i)$ is encountered in X^ℓ

$$h(\mathbf{x}_i)^{[y_i=+1]} + (1 - h(\mathbf{x}_i))^{[y_i=-1]}$$

- Entire X^ℓ likelihood:

$$L(X^\ell) = \prod_{i=1}^{\ell} h(\mathbf{x}_i)^{[y_i=+1]} + (1 - h(\mathbf{x}_i))^{[y_i=-1]}$$

is often written via log-likelihood (of which the negative is log-loss)

$$\log L(X^\ell) = \sum_{i=1}^{\ell} [y_i = +1] \log h(\mathbf{x}_i) + [y_i = -1] \log(1 - h(\mathbf{x}_i))$$

The logistic regression model

- The choice of h: sigmoid function

$$h(\mathbf{x}) = \sigma(\mathbf{w}^\intercal \mathbf{x})$$

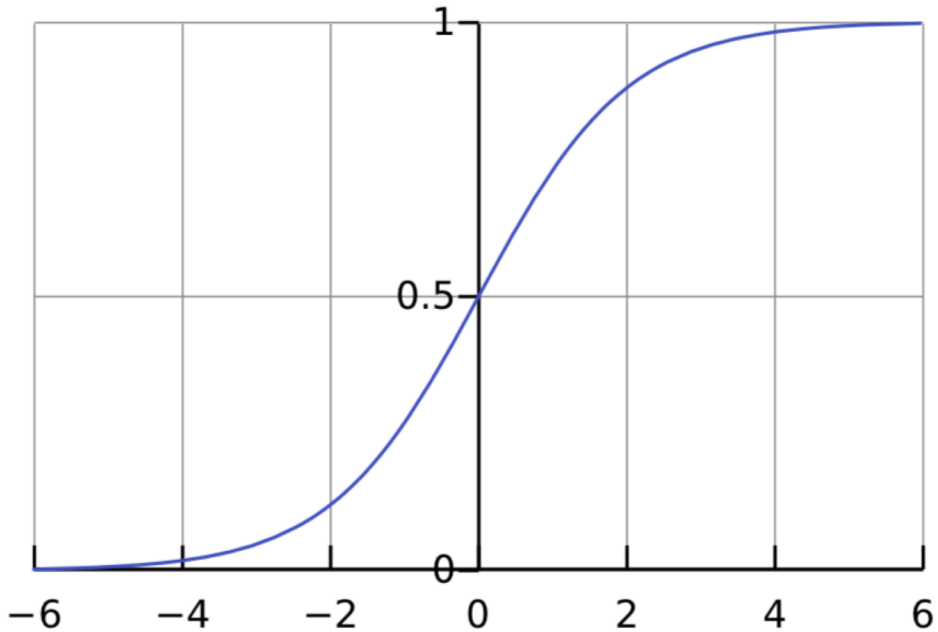
where $\sigma(x) \in [0, 1]$

- Typical choice: the logistic function

$$\sigma(\mathbf{w}^\intercal \mathbf{x}) = \frac{1}{1 + \exp(-\mathbf{w}^\intercal \mathbf{x})}$$

- Plugging the logistic function into the loss yields

$$\sum_{i=1}^{\ell} (1 + \exp(\mathbf{w}^\intercal \mathbf{x})) \to \min_{\mathbf{w} \in \mathbb{R}^d}$$



Logistic regression model demo

http://arogozhnikov.github.io/LogisticRegression.html

Figures of Merits

Classification quality evaluation: accuracy

- Given a labeled sample $X^\ell = \left\{(\mathbf{x}_i, y_i)\right\}_{i=1}^{\ell}$, $y_i \in \{-1, +1\}$, and some candidate h, how well does h perform on X^ℓ?
- Let $a(x) = [h(x) > t]$
- Obvious choice: accuracy

$$\text{accuracy}(a, X^\ell) = \frac{1}{\ell}\sum_{i=1}^{\ell}[a(\mathbf{x}_i) = y_i]$$

- Bad for imbalanced data: for $\ell = 1000$,
  $n_- = \sum_{i=1}^{\ell}[y = -1] = 50$, $n_+ = \sum_{i=1}^{\ell}[y = +1] = 950$,
  a trivial rule $h(\mathbf{x}) = +1$ would yield $\text{accuracy}(a, X^\ell) = 0.95$

Classification quality: confusion matrix

	$y = 1$	$y = -1$
$a(x) = 1$	True Positive (TP)	False Positive (FP)
$a(x) = -1$	False negative (FN)	True Negative (TN)

- More informative criteria:

$$\text{precision} = \frac{\text{TP}}{\text{TP} + \text{FP}},$$

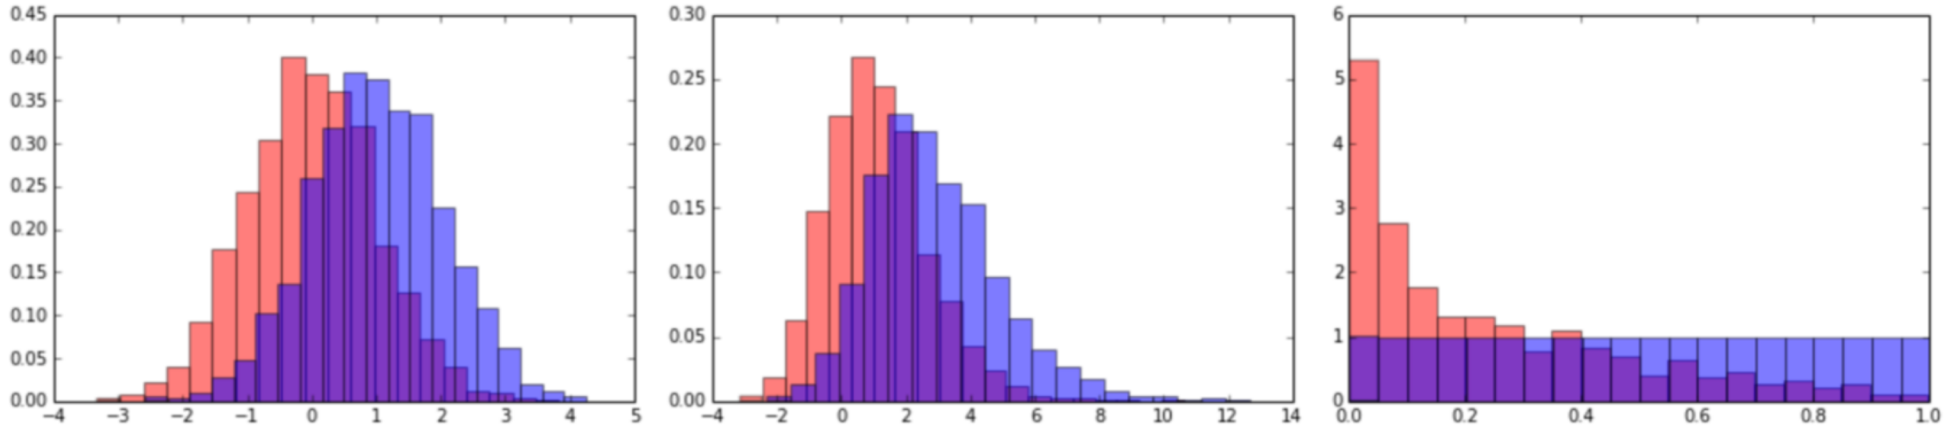
$$\text{recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

- While accuracy can be expressed, too

$$\text{accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{FP} + \text{FN} + \text{TN}}$$

Measuring quality of binary classification

The classifier's output in binary classification is real variable (say, signal is blue and background is red)



- Which classifier provides better discrimination?
- Discrimination is identical in all three cases

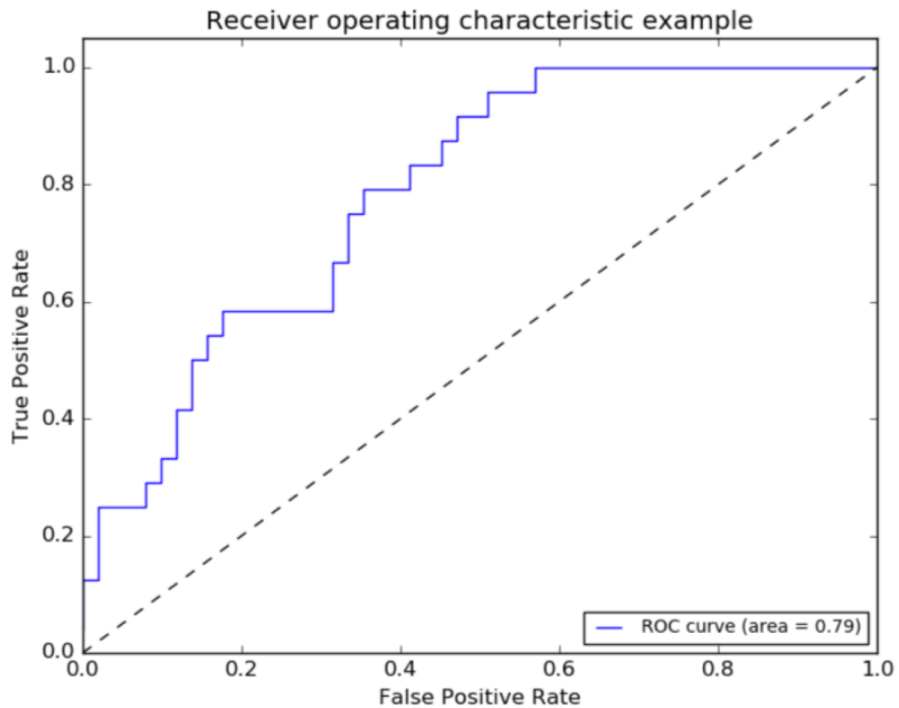
Classification quality: operating curves

- Often $h(\mathbf{x})$ is more valuable than its thresholded version $a(x) = [h(x) > t]$
- Consider two-dimensional space with coordinates

$$\text{FPR} = \frac{\text{FP}}{\text{FP} + \text{TN}}, \qquad \text{TPR} = \frac{\text{TP}}{\text{TP} + \text{FN}},$$

  corresponding to various choices of the threshold t
- The plot TPR(FPR) is called the receiver operating characteristic (or ROC) curve

Receiver operating characteristic curve



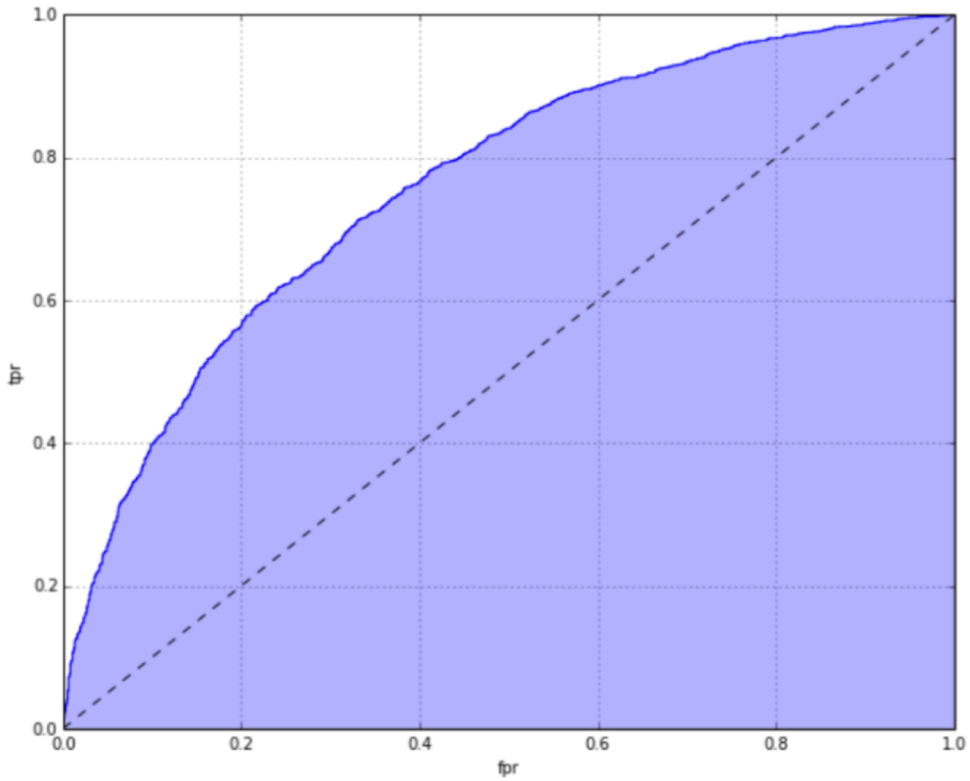
https://arogozhnikov.github.io/RocCurve.html

ROC Curve

- Defined only for binary classification
- Contains important information: all possible combinations of signal and background efficiencies you may achieve by setting a threshold
- Particular values of thresholds (and initial pdfs) don't matter, ROC curve doesn't contain this information
- ROC curve = information about order of observations' predictions:
  `b b s b s b ... s s b s s`
- Comparison of algorithms should be based on the information from ROC curve

Area Under ROC Curve - ROC AUC

$ROCAUC = P(r_b < r_s)$ where r_b , r_s are predictions for random background and signal observations.

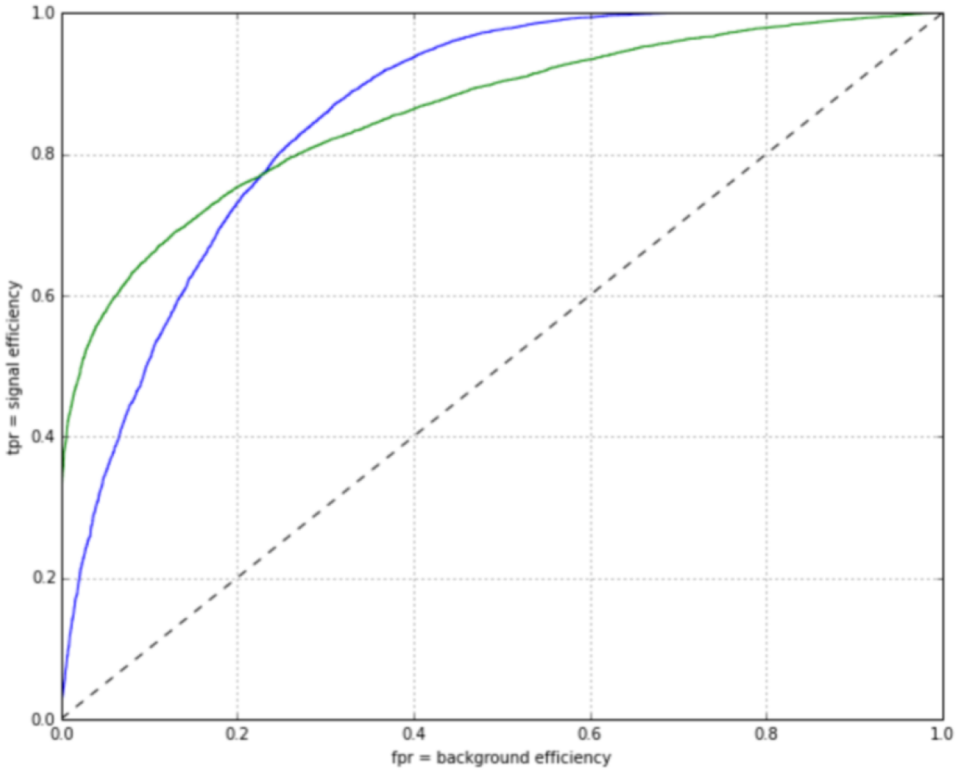


ROC Curve - comparison

Classifier have the same ROC AUC, but which is better ...

- if the problem is spam detection? (putting normal letter in spam is very undesireable)
- for background rejection system at the LHC? (we need to pass very few background)

Applications frequently demand different metric.

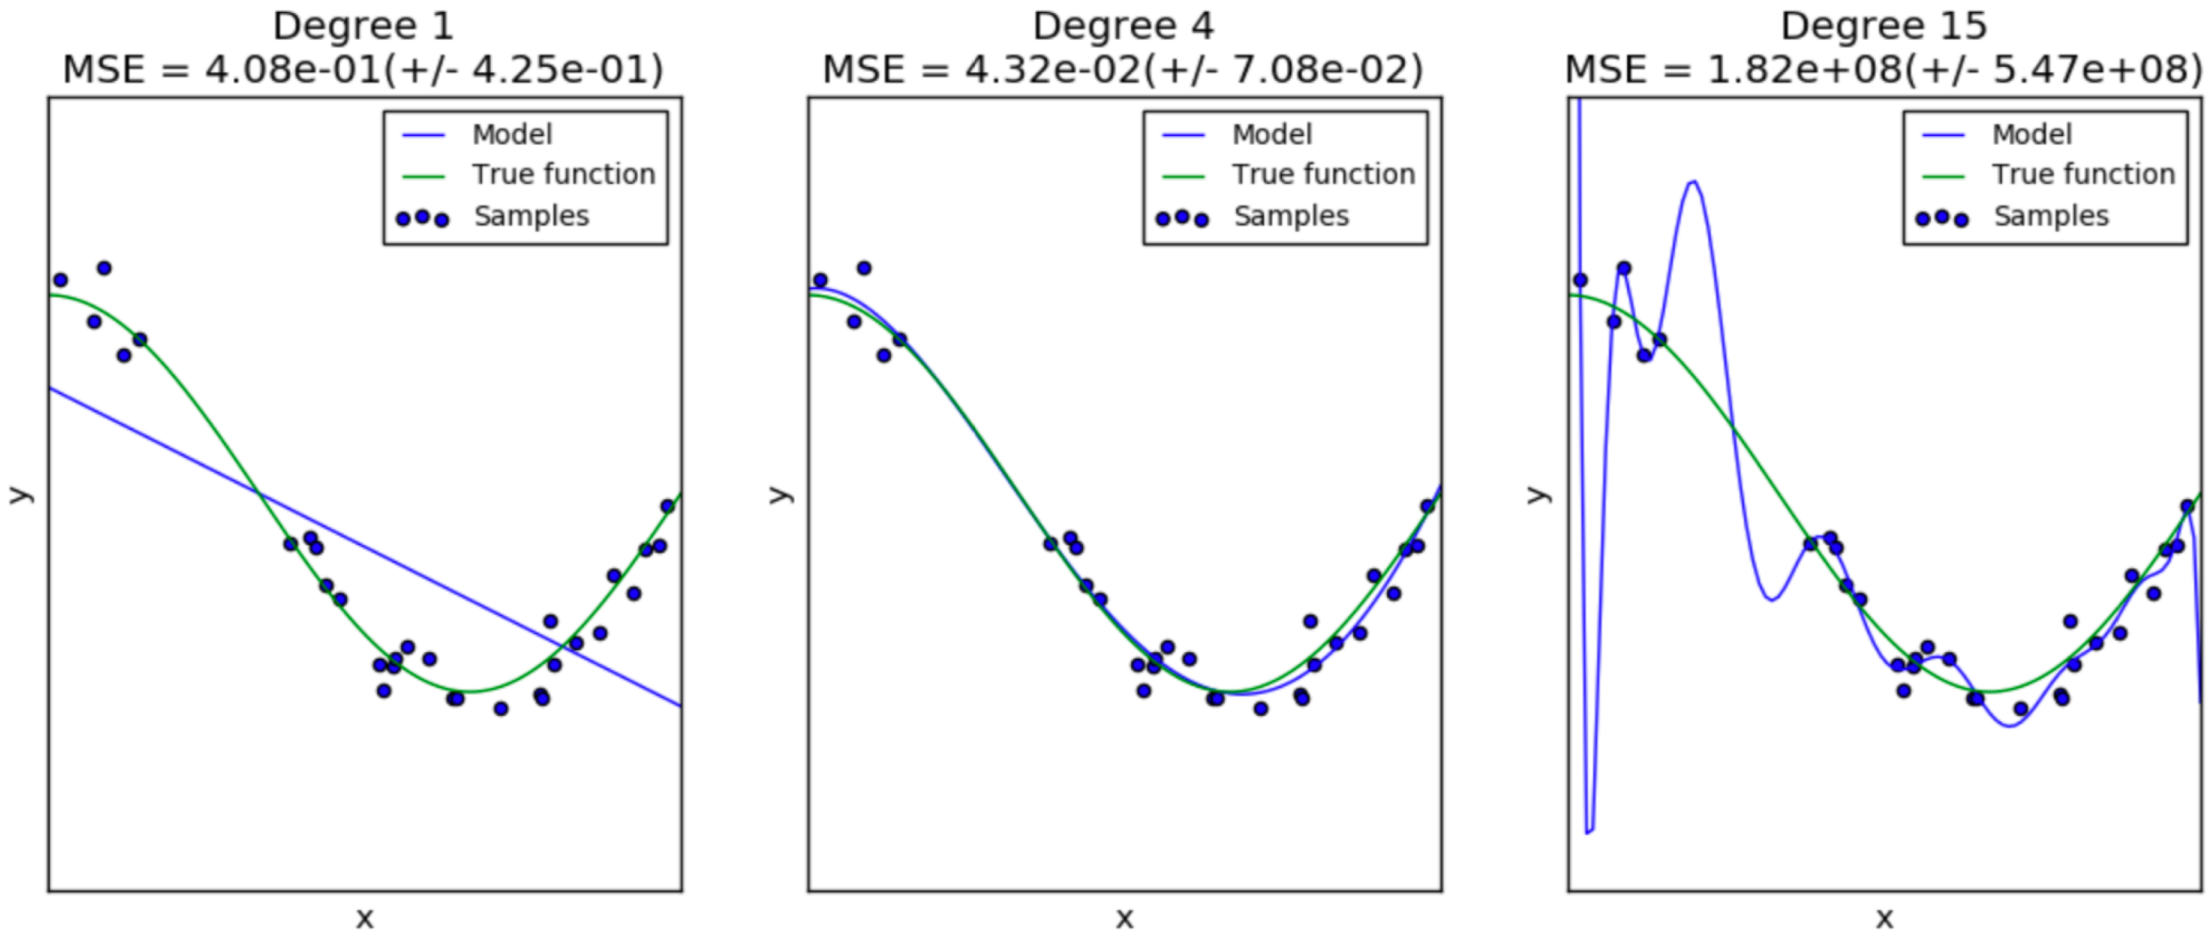


Overfitting

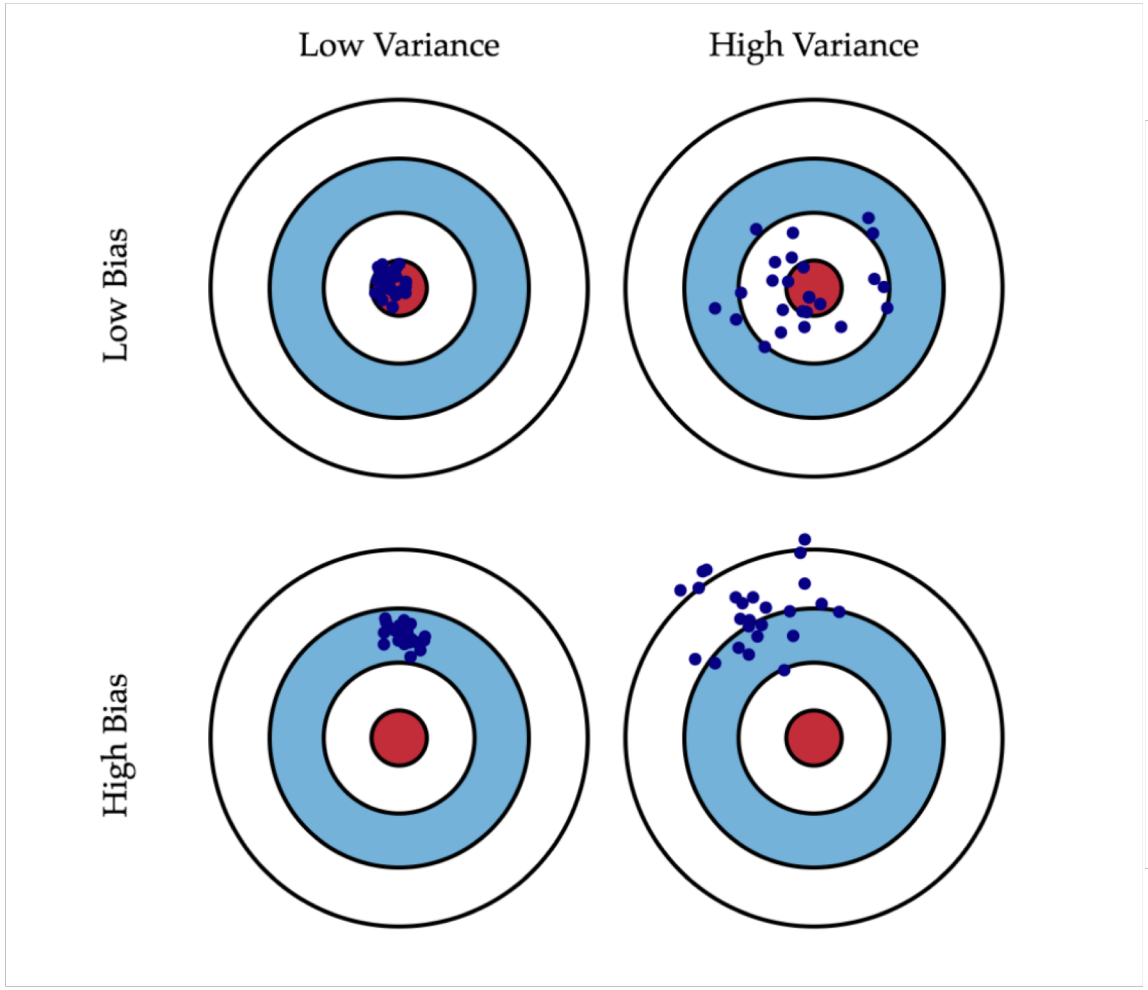
Generalization and overfitting

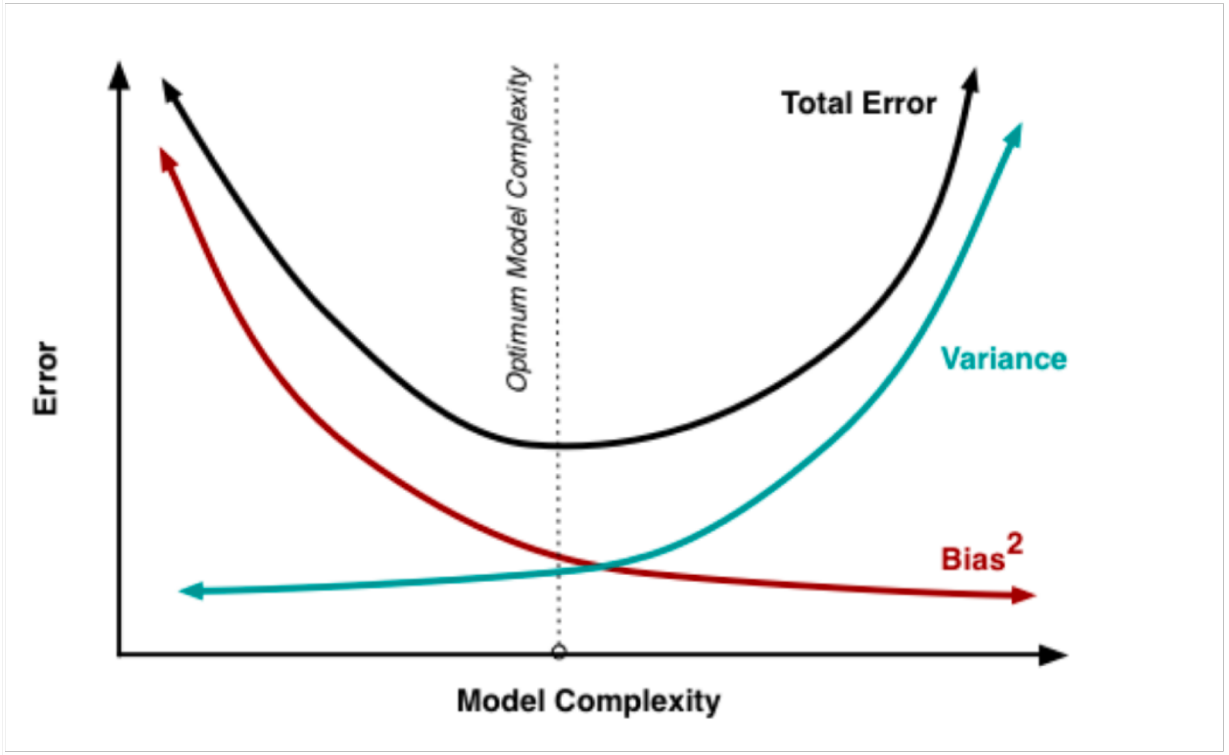
- Training set memorization: for seen $(\mathbf{x}, y) \in X^\ell$, $h(\mathbf{x}) = y$
- Generalization: equally good performance on both new and seen instances
- How to assess model's generalization ability?
- Consider an example:
  - $y = \cos(1.5\pi x) + \mathcal{N}(0, 0.01)$, $x \sim \text{Uniform}[0, 1]$
  - Features: $\{x\}$, $\{x, x^2, x^3, x^4\}$, $\{x, \ldots, x^{15}\}$
- How well do the regression models perform?

Polynomial fits of different degrees



Bias-Variance Trade-off

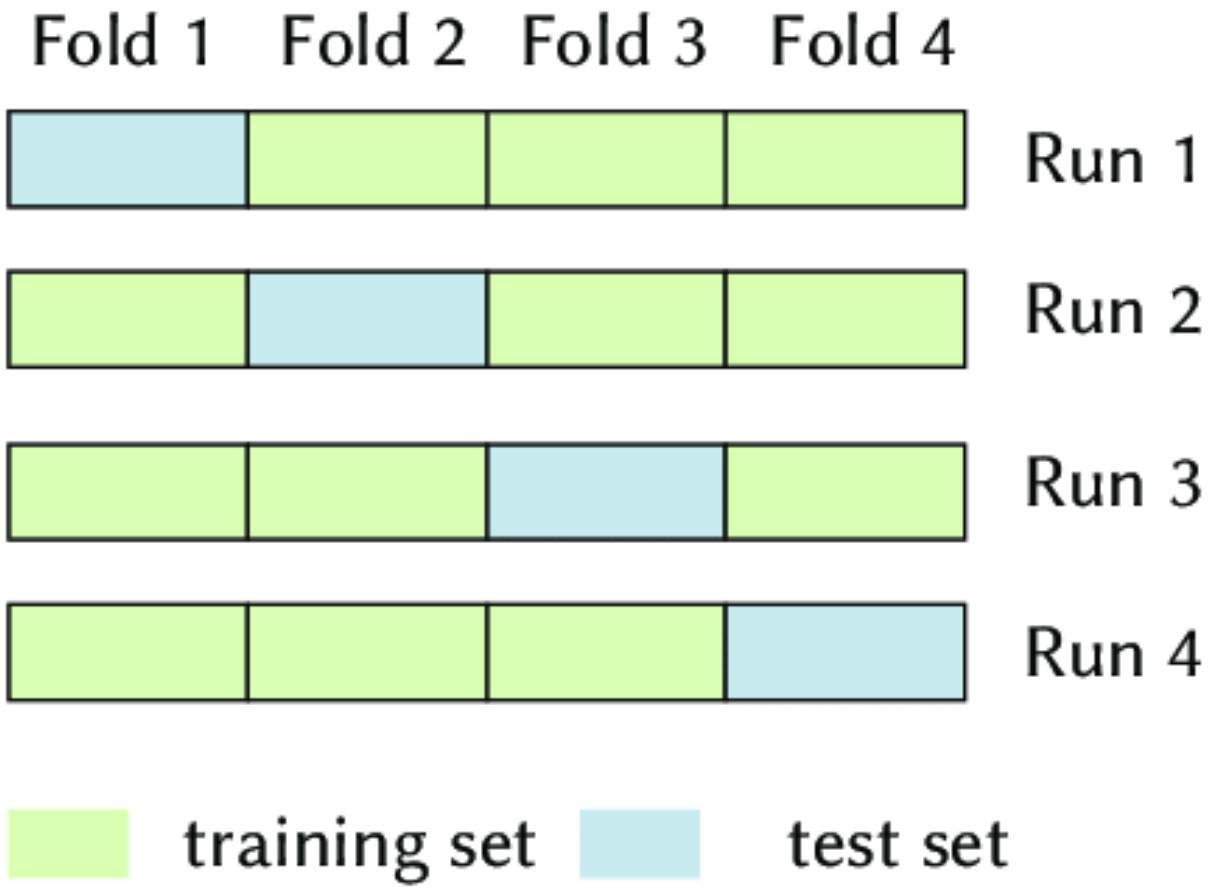




Assessing generalization ability: cross-validation

- Split training set into subsets of equal size $X^\ell = X_1^\ell \cup \ldots \cup X_K^\ell$
- Train K models $h_1, \ldots, h_K$ where each model h_k is trained on all subsets but X_k^ℓ
- Assess quality using $\mathrm{CV} = \frac{1}{K} \sum_{k=1}^{K} Q(h_k, X_k^\ell)$ (K-fold)
- Leave-one-out cross-validation: $X_k^\ell = \{(\mathbf{x}_k, y_k)\}$

K-fold cross-validation



Regularization

Ad-hoc regularization: motivation

› Consider the multivariate linear regression problem with $\boldsymbol{X} \in \mathbb{R}^{d \times d}$

$$\|\boldsymbol{y} - \boldsymbol{X}\mathbf{w}\|^2 \to \min_{\mathbf{w} \in \mathbb{R}^d}$$

› Analytic solution involves computing the product $\boldsymbol{R} = (\boldsymbol{X}^\intercal \boldsymbol{X})^{-1}\boldsymbol{X}^\intercal$

› If $\boldsymbol{X} = \text{diag}(\lambda_1, \ldots, \lambda_d)$ with $\lambda_1 > \lambda_2 > \ldots > \lambda_d \to 0$ (meaning we're in eigenbasis of $\boldsymbol{X}$) then

$$\begin{aligned}
\boldsymbol{R} = (\boldsymbol{X}^\intercal \boldsymbol{X})^{-1}\boldsymbol{X}^\intercal = \\
= \Big(\text{diag}(\lambda_1, \ldots, \lambda_d)\text{diag}(\lambda_1, \ldots, \lambda_d)\Big)^{-1}\text{diag}(\lambda_1, \ldots, \lambda_d) = \\
= \text{diag}\left(\frac{1}{\lambda_1}, \ldots, \frac{1}{\lambda_d}\right), \quad \text{leading to huge diagonal values in } \boldsymbol{R}
\end{aligned}$$

Ad-hoc regularization: L2

- **Regularization:** replace fit with fit + penalty as in

$$Q(\mathbf{w}) \to Q_\alpha(\mathbf{w}) = Q(\mathbf{w}) + \alpha R(\mathbf{w})$$

- $R(\mathbf{w})$ is called the regularizer, $\alpha > 0$ — the regularization constant
- Regularized multivariate linear regression problem

$$\|\boldsymbol{y} - \boldsymbol{X}\mathbf{w}\|^2 + \alpha\|\mathbf{w}\|_2^2 \to \min_{\mathbf{w}\in\mathbb{R}^d}$$

- Regularized analytic solution available

$$\mathbf{w}^* = (\boldsymbol{X}^\intercal\boldsymbol{X} + \alpha\boldsymbol{I})^{-1}\boldsymbol{X}^\intercal\boldsymbol{y}$$

Why L2 regularization works

› Analytic solution: compute the regularized operator

$$\boldsymbol{R} = (\boldsymbol{X}^\intercal \boldsymbol{X} + \alpha \boldsymbol{I})^{-1} \boldsymbol{X}^\intercal$$

› If $\boldsymbol{X} = \text{diag}(\lambda_1, \ldots, \lambda_d)$ with $\lambda_1 > \lambda_2 > \ldots > \lambda_d \to 0$ (meaning we're in eigenbasis of $\boldsymbol{X}$) then

$$\begin{aligned}
\boldsymbol{R} &= (\boldsymbol{X}^\intercal \boldsymbol{X} + \alpha \boldsymbol{I})^{-1} \boldsymbol{X}^\intercal = \\
&= \Big(\text{diag}(\lambda_1, \ldots, \lambda_d)\text{diag}(\lambda_1, \ldots, \lambda_d) + \text{diag}(\alpha, \ldots, \alpha)\Big)^{-1} \text{diag}(\lambda_1, \ldots, \lambda_d) = \\
&= \text{diag}\left(\frac{\lambda_1}{\lambda_1^2 + \alpha}, \ldots, \frac{\lambda_d}{\lambda_d^2 + \alpha}\right),
\end{aligned}$$

smoothing diagonal values in $\boldsymbol{R}$

More regularizers!

- L2 regularized multivariate linear regression problem

$$\|\boldsymbol{y} - \boldsymbol{X}\mathbf{w}\|^2 + \alpha\|\mathbf{w}\|^2 \to \min_{\mathbf{w}\in\mathbb{R}^d}$$

- L1 regularized regression (LASSO)

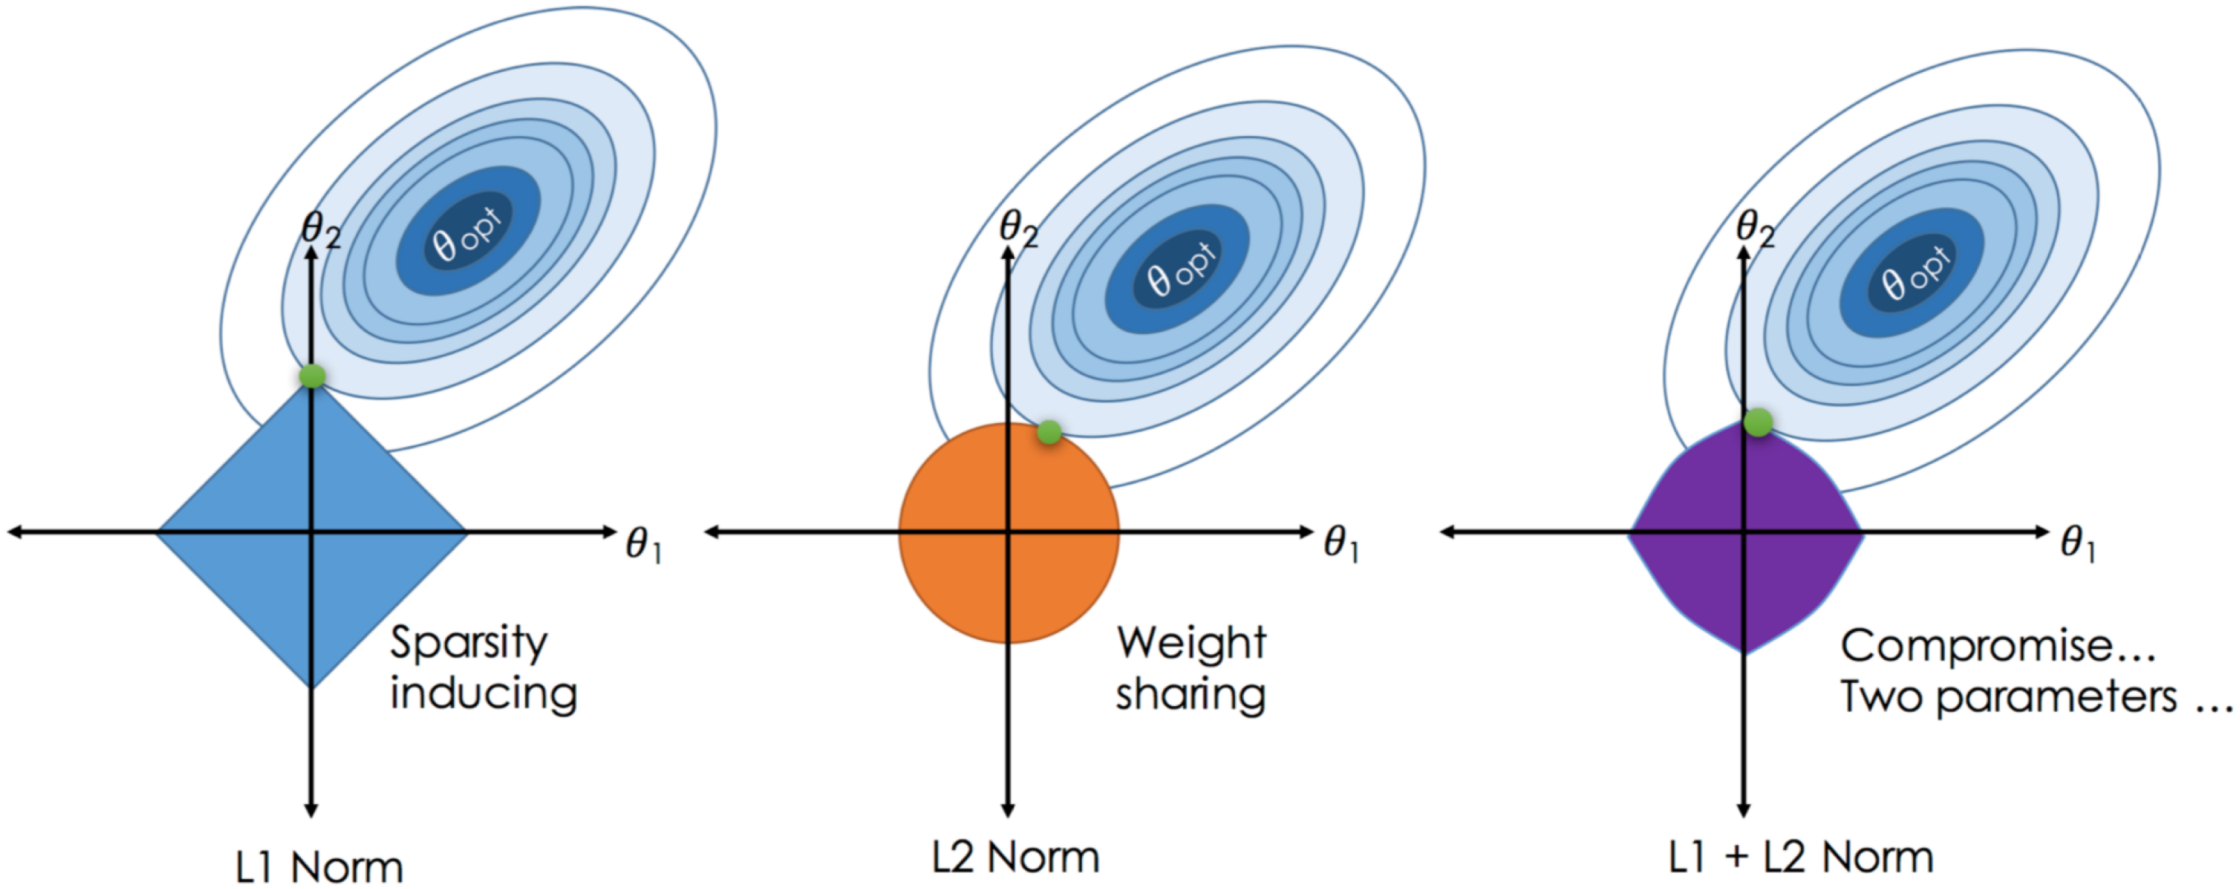
$$\|\boldsymbol{y} - \boldsymbol{X}\mathbf{w}\|^2 + \alpha\|\mathbf{w}\|_1 \to \min_{\mathbf{w}\in\mathbb{R}^d}$$

- L1/L2 regularized regression (Elastic Net)

$$\|\boldsymbol{y} - \boldsymbol{X}\mathbf{w}\|^2 + \alpha_1\|\mathbf{w}\|_1 + \alpha_2\|\mathbf{w}\|_2^2 \to \min_{\mathbf{w}\in\mathbb{R}^d}$$

- Convex $Q(\mathbf{w})$: unconstrained optimization $Q(\mathbf{w}) + \alpha\|\mathbf{w}\|_1$ is equivalent to constrained problem $Q(\mathbf{w})$ s.t. $\|\mathbf{w}\|_1 \leqslant C$

Geometric interpretation of regularizers



Another interpretation of regularizers

Figure: Large parameter space

Figure: Regularized models

Conclusion:

- Linear model – one of the simplest but quite popular
- Can be used for both regression and classification
- Figure of Merits: meaning of area under ROC curve
- Indicators of overfitting and how to deal with it
